

Comparison of R134a and R1234ze for New Chiller Systems and for Fluid (Drop-In) in Existing Systems

Francis A. Di Bella, P.E.

Adam Weaver

Colin Osborne

Executive Summary

A chiller cycle analysis is presented that identifies the relative performance of refrigerants R134a and R1234ze for drop-in or new chiller applications. The study reveals that there is a 30% increase in the volumetric flow rate for new chillers using R1234ze, compared to R134a for the same chiller capacity. The C.O.P. is comparable for the two refrigerants on new systems but may likely be reduced when R134a is exchanged for R1234ze on existing systems. A comparison of the compressor size and speed is also presented and indicates the R1234ze chiller compressor is larger in size and operates at a lower speed (rpm) for the same chiller capacity. For a simple replacement of R134a refrigerant with R1234ze into existing chiller systems, the C.O.P. will be reduced by 16-18%.

Background of Current Work

The heating, ventilating, and air conditioning (HVAC) industry is rapidly proceeding to the use of R1234ze and other similar earth-friendly refrigerants in new systems and abandoning the more conventional refrigerant, R134a. R134a came into prominent use as a substitute for R11 and later then R22 as a result of the Montreal Protocol that identifies R11 and R22 as ozone depletion gases. Table I summarizes the ozone depletion potential and the global warming potential for some of the contemporary chiller refrigerants in use today. Although R134a and the other proposed refrigerant substitutes shown in Table I are not considered fluids that contribute to the depletion of the ozone, the recommended fluids do have a significant impact on the global warming. The adoption of R1234ze as a refrigerant for use in HVAC systems is seen as a means of significantly reducing global warming, while also having little to no effect on ozone depletion.

R1234ze(E) (trans-1,3,3,3-Tetrafluorprop-1-ene; $\text{CF}_3\text{CH}=\text{CHF}$) is considered part of the HFO (hydrofluoroolefin) family. The extremely low Global Warming Potential (GWP) value (less than 1) of R1234ze is its most significant physical characteristic. It is considered by ASHRAE as a mildly flammable fluid at temperatures above 30°C. The manufacturer of R1234ze also suggests careful attention to the choice of materials and lubricants that are used with the refrigerant. For example, attention is given to the unsuitability of acrylics used with the R1234ze and under some conditions contact with neoprene and polypropylene must be given careful attention. Polyester oils are recommended as the lubricant for compressor bearings or other mechanical systems used in the chiller that use R1234ze as the refrigerant. It is strongly suggested that the operational guidelines of the compressor manufacturer be observed when the R1234ze is to be used as a drop-in fluid in an existing chiller system that was using R134a.

TABLE I. Comparison of Contemporary Refrigerant Fluids with respect to GWP and ODP. (note: R11 is given the OZD ranking of 1 due to its being the worse contributor to ozone depletion)

REFRIGERANT	GLOBAL WARMING POTENTIAL	OZONE DEPLETION POTENTIAL
R407C	1774	0
R134A	1300	0
R410A	1924	0
R513A	572	0
R1233ZD	1	0
R1234ZE	LESS THAN 1	0

As a leading independent, turbomachinery engineering-design company and manufacturer of prototype compressors, Concepts NREC (CN) is studying the application of R1234ze in chiller systems in order to adjust and improve on the design of compressors that must work with the new fluid. This paper presents some of the most basic of results, when comparing the performance of R1234ze with the current conventional refrigerant: R134a. The analysis presented in this paper consists of two Case Studies:

- A. Comparing the performance of each of the fluids with an assumption that the specific speed (N_s) is theoretically optimized for a basic chiller (vapor compression cycle) and a chiller cycle that utilizes an economizer (also sometimes called a cascade system). In this comparison, the efficiency of the compressor is kept at the same value of 85% and the diameter of the compressor impeller and speed are determined from a theoretical Specific Speed (N_s) and Specific Diameter (D_s) notational analysis. The theoretical compressor (Total-to-Static) adiabatic efficiency vs. Specific Speed is shown in Figure 1. This theoretical presentation has been prepared by CN based on generic radial compressor research and compares very favorably with independent, published compressor analysis by others, as noted in Figure 1. This comparison is consistent with the engineering task of designing a “new” chiller system that is specifically designed to use R1234ze. The alternative solution is to use the existing R134a chiller hardware and simply replace the R134a with the new fluid, R1234ze. The simple replacement of one fluid with another in an installed and operating chiller system is often called a “Drop-In”

fluid application. This simple solution comes with a significant performance penalty as the “old” R134a compressor impeller must now compress a different fluid; an inherently less efficient compression process.

- B. Determining the performance of a compressor using R1234ze, if it is used to replace the R134a refrigerant, using the compressor components for which the chiller was initially designed with R134a. In this study, the “old” R134a compressor speed and diameter are not changed and a new N_s and D_s are calculated for the R1234ze refrigerant operating at the necessary pressure ratios. The change in the refrigerant causes the “old” design to not be the optimum for the R1234ze fluid as defined by the optimum N_s and D_s . This ultimately effects the compressor efficiency and, depending on the severity of the change in the C.O.P. due to the change in the compressor efficiency change, the condenser heat exchanger size may also be undersized with the R1234ze. In this case, the pressure ratio across the compressor may increase, which would also decrease the C.O.P. for this “Drop-In” R1234ze application. However, it was determined from this study that the small increase of 2-3% in heat transfer would not significantly change the hot and cold temperature profiles in the condenser based on the engineering practice to have considerable performance margins designed into the heat exchanger. The off-design efficiency for the R1234ze fluid operation is determined by forcing the N_s and D_s to change until the speed and diameter of the R1234ze compressor matches the “old” R134a chiller compressor specifications. The new iterated value of N_s is then used with Figure 1 to determine a rerate for the compressor efficiency. This new compressor efficiency is then rerated based on the ratio of the “old” compressor diameter and what the diameter of the compressor should be with the R1234ze. With the corrected compressor efficiency now determined, the chiller cycle is recalculated.

The analysis proceeded by adopting the ASHRAE guideline for conventional HVAC chiller applications. This guideline is summarized in Table II.

Target Design Conditions

3.1 Full Load Design point:

The full load design point is based on a water chiller operating at standard ARI-550/590-2003 conditions:

Evaporator = 12.2°C/ 6.67°C/ 0.56K approach, 0.043l/sec per evaporator kW.

Condenser = 29.44°C/ 34.57°C/ 0.7K approach, 0.054l/sec per evaporator kW. Discharge piping loss less than 10kPa.

The full load design point must comply with Ashrae 90.1 full load requirement for both the 2004 editions and 2010; of these two the 2004 has the most stringent requirement with a 6.11COP limit (0.576kW/ton).

The cycle analysis includes the use of an integrated, hermetically sealed, electric motor drive that uses the refrigerant to cool the motor jacket and internal windings. For this analysis, the efficiency for the motor was taken to be 95%. The heat rejected from the motor equally is divided equally between the jacket and the motor internal windings, sometimes called the motor winding cooling gap. It was also assumed that the vapor cooling the motor winding gap was heated to a superheat temperature of 25°F (14°C). The refrigerant cooling is returned to the chiller system. Thus, the chiller system is closed with respect to maintaining its inventory of refrigerant.

Commented [AS1]: Mistake??

Two chiller design configurations were analyzed with each fluid:

1. The basic or simple vapor compression refrigeration system that consists of four basic components: a one-stage compressor, evaporator, condenser and throttle valve. This cycle is diagrammed in Figure 2A.
2. A cascade chiller design often called an economizer chiller system that consists of the same basic components but also includes a single flash tank (used for this study) and a two-stage compressor. The vapor from the flash tank is injected into the inlet of the second stage. This cycle is diagrammed in Figure 2B.

Results of Analysis for Case Study A: Designing new Chillers with either R134a or R1234ze

Tables III and IV present a summary of the cycle analysis for new R134a and R1234ze chiller systems, assuming that each was designed for a new application. Thus, the 85% efficiencies for the compressor are assumed to be achievable with the speed and diameter of the compressor shown. The speed and diameter are based on a Specific Speed of 105 and a specific diameter equal to 1.5. The simple, vapor compression system comparison of the performance between R134a and R1234ze, shown in Table III, is sized for a cooling capacity of 400RT. The complete cycle state points for Table III are shown in Figures 3 and 4. The economizer (cascade) system comparison of the same fluids is sized for a cooling capacity of 700RT and the result is summarized in table IV.

TABLE III. Comparison of R134a and R1234ze at 400RT operating on a basic chiller cycle without (no economizer) with same Specific Speed (Ns) (Figures 3 and 4)

400RT capacity	R134A	R1234ze
COP	6.58	6.57
\dot{M}_1 AND \dot{M}_2 [kg/s]	8.75; 8.84	9.52; 9.61
\dot{V}_1 AND \dot{V}_2 [m ³ /s]	0.50; 0.21	0.67; 0.27
P1 [bar,a]	3.6	2.67
P ₃ [bar,a] ; T ₃ [C]	9.05 ; 43.1	6.82 ; 38.3
Compressor efficiency	0.85	.85
Ns and Ds	105 and Ds = 1.5	105 and Ds = 1.5
Diameter [m]	0.22	.254
Speed [rpm]	15,500	12,600

TABLE IV. Comparison R134a and R1234ze 700RT Chiller Performance with Economizer (from Figures 5 and 6)

700 RT capacity	R134A	R1234ze
COP	6.79	6.57
\dot{M}_1 AND \dot{M}_2 [kg/s]	14.4 ; 15.4	15.6 ; 16.75
\dot{V}_1 AND \dot{V}_2 [m ³ /s]	0.82 ; 0.52	1.09 ; 0.69
P1 & P2 [bar,a]	3.6 & 6.29	2.67
P ₃ [bar,a] ; T ₃ [C]	9.05 ; 44.4	6.82 ; 39.7
Compressor efficiencies (η1 & η2)	0.85 & 0.85	0.85 & 0.85
Ns ₁ &Ns ₂ and Ds _{1,2}	105 & 92 and Ds _{1,2} = 1.5	105 & 88 and Ds _{1,2} = 1.5
Diameters, D1 & D2 [m]	0.32 & 0.23	.37 & .27
RPM	8,100	6,600

Several critical observations can be made from a study of Tables III and IV

1. The C.O.P. for a simple vapor compression system, using R134a and R1234ze, is very comparable.
2. The volume flow rate for the R1234ze system is 30-35% more than the R134a system for the same capacity. The mass flow rate for the R1234ze system is 8-9% higher than the mass flow rate for the R134a chiller.
3. The diameter for the R1234ze system compressor is 15% larger than the compressor diameter for the R134a.
4. The speed for the R1234ze system compressor is 18-20% less than the R134a compressor speed.

Results of Analysis for Case Study B: Using Existing R134a Chiller but replacing fluid with R1234ze

Tables V and VI present a summary of the cycle analysis assuming that an existing R134a chiller has its fluid replaced with R1234ze, with no additional changes to the mechanical components. Thus, the initial 85% optimum design point efficiency for the compressor is changed according to the aerodynamic characteristics of the new refrigerant. The speed and diameter are assumed to not change with the new R1234ze replacement. Thus, the N_s and D_s for the existing compressor impellers are off-design. The simple, vapor compression system comparison of the performance between R134a and the DROP-IN R1234ze is shown in Table VI for a cooling capacity of 400RT. The complete cycle state points are shown in Figure 8.

TABLE V. 700RT R1234ze DROP-IN to a R134a Chiller (Figure 7)

700 RT capacity	R134A (existing system-Fig. 4)	R1234ze (Fig. 7)
COP	6.79	5.63
\dot{M}_1 AND \dot{M}_2 [kg/s]	14.4 ; 15.4	15.54 ; 16.75
\dot{V}_1 AND \dot{V}_2 [m ³ /s]	0.82 ; 0.52	1.09 ; 0.69
P1 & P2 [bar,a]	3.6 & 6.29	2.67 & 4.66
P ₃ [bar,a] ; T ₃ [C]	9.05 ; 44.4	6.82 ; 42.5
Compressor efficiencies (η_1 & η_2)	0.85 & 0.85	0.70 & 0.74
N_{s1} & N_{s2} and D_s	105 & 92 and $D_s = 1.5$	129 & 109 and $D_s = 1.29$
Diameters, D1 & D2 [m]	0.32 & 0.23	.32 & .23
RPM	8,100	8,100

TABLE VI. 400RT R1234ze DROP-IN to a R134a Chiller (Figure 8)

400RT capacity	R134A (existing System-Fig. 5)	R1234ze (Fig. 8)
COP	6.58	5.7
\dot{M}_1 AND \dot{M}_2 [kg/s]	8.75; 8.84	9.52; 9.62
\dot{V}_1 AND \dot{V}_2 [m ³ /s]	0.50; 0.21	0.67; 0.27
P1 [bar,a]	3.6	2.67
P ₃ [bar,a] ; T ₃ [C]	9.05 ; 43.1	6.82 ; 41.4
Compressor efficiency	0.85	.74
Ns and Ds	105 and 1.5	127 and 1.3
Diameter [m]	0.22	.22
Speed [rpm]	15,500	15,500

Several critical observations can be made from a study of Tables V and VI

1. The C.O.P. for a Drop-In of R1234ze in a R134a chiller is reduced by 13-17% for the full-load capacity. Although not demonstrated in this paper, it is likely that the replacement fluid: R1234ze used with the “old” (R134a) compressor will present control issues at cooling capacities less than 35%.
2. The volume flow rate for the R1234ze system is 30-35% more than the R134a system for the same refrigeration capacity. The mass flow rate for the R1234ze system is 8-9% higher than the mass flow rate for the R134a chiller.
3. The condenser for the R1234ze chiller will be undersized by 2-3 % due to the lower C.O.P.

Conclusions

There is an emphasis by regulatory authorities throughout the world to continue to protect the environment from global warming by changing the refrigerant in chillers from R134a to R1234ze. This objective is encouraged by the successful worldwide effort to reduce the damage to the ozone layer over the last several decades. There is an industrial consensus that R1234ze is a very attractive replacement fluid, causing little to no contributions to global warming. The results shown in this paper indicate that new chiller units used in HVAC systems that are designed for use with R1234ze will achieve very comparable C.O.P. performance to the “older” R134a chiller designs. However, the simple replacement (or Drop-In) of R1234ze into existing chiller systems that were designed for use with R134a will have a 13% to 17% reduction in C.O.P. performance at the full capacity design point.
